2. SYSTEM ANALYSIS

2.1 GENERAL

The bridge is built using reinforced concrete.

The bridge is designed as frame bridge with longitudinal beams in superstructure.

Stiffness of bridge deck in longitudinal direction is verified by determining effective width due to shear lag.

Abutments are defined by using shell elements applied to nodal surface in abutments.

Bridge deck is defined by using shell elements applied to nodal surface in superstructure.

Longitudinal beams are defined using beam elements applied to nodal line in superstructure.

Longitudinal beam will be connected to bridge deck using rigid constraints (= Tied Mesh).

FEM-program has the capability of analysing several different static systems within one FEM-model. This bridge use two different analysis (*Analysis 1* & *Analysis 2*). The geometry is the same for both, however the rigid constraints used in superstructure vary.
Analysis 1 is called “Base Analysis”. All changes in *Analysis 1* are based on changes from *Analysis 1*. Evaluation of traffic is performed on *“Base Analysis”*.

For load cases shrinkage (KRYMP) and temperature (TEMP) each longitudinal beam is attached one line of nodes in superstructure. This to avoid large internal forces in deck due to prevented contraction in transversal direction. These loads are performed in *Analysis 2*.

For all other load cases each longitudinal beam is attached two lines of nodes in superstructure. The reason for this is to get correct load effect in transversal direction, since with only one line the span length for deck would be too long. These loads are performed on *Analysis 1*.

Entire structure is modelled using isotropic material.

Bridge foundation consists of compacted gravel.

Wingwalls are not modelled statically since considered inactive in vertical direction. This is due cracking and the use of only minimal reinforcement in this direction.

Edge beams are not modelled statically since considered inactive. This assumption is considered on safe side. The assumption will facilitate future replacement of edge beams.

Bottom of abutments will be connected to fictive rigid beams using rigid constrains (= Tied Mesh). The rigid beams will have infinite stiffness in all directions apart from axial. In this direction stiffness will be negligible.

The end of longitudinal beams in superstructure are only to substructure to one node at location where each nodal line meets the shell elements in the abutments. To spread forces to substructure as accurately as possible fictious rigid beams are introduced at these connection points. The rigid beams (=Rigid beam superstructure) will have infinite stiffness in all directions apart but axial. In this direction stiffness will be negligible.

At bottom of abutments a fictitious rigid beam (= Rigid beam abutment) with infinite stiffness in all directions apart from axial. In this direction stiffness will be negligible. In the middle of this fictious rigid beam a super node will be connected. This to retrieve reactions a single point for every support.

Shell elements are used to define Superstructure end zone. To be able to apply prestress tendons in this area fictitious beams (= Weak beam superstructure) are applied with negligible stiffness in all directions.

In system analysis gross cross section may be used for longitudinal beams in superstructure, see SS-EN 1992-1-1 section 5.3.2.1 point (4).

In FEM-analysis constant cross section is used for longitudinal beams along entire span length, see SS-EN 1992-1-1 section 5.3.2.1 (4).

The difference in stiffness between conventionally reinforced construction elements shall be considered for statically indeterminate prestressed concrete structures. According to older technical practice, the stiffness for conventionally reinforced construction elements is 60% of that applicable to prestressed construction elements. This interpretation aligns with what is stated in TRVINFRA-003331 section 10.1.2.2. This technical practice is applied to the studied bridge.

The difference in stiffnesses is handled by using 60 % of E-modulus for shells in substructure.

For the deck in superstructure the 60 % of E-modulus in transversal direction is used. In the longitudinal direction 100 % of E-modulus is considered. This requirement requires use of orthotropic material.

For longitudinal beams in superstructure 100 % of E-modulus is considered.

Rotational stiffness of foundation is determined using software PROG G3.005.

Since the distance to solid ground (H) is less than twice the width of the bottom plate (2B), the method according to TRVINFRA-00227 appendix B5.1 is not applicable. Instead, a derived method for cases where H < 2B is used.

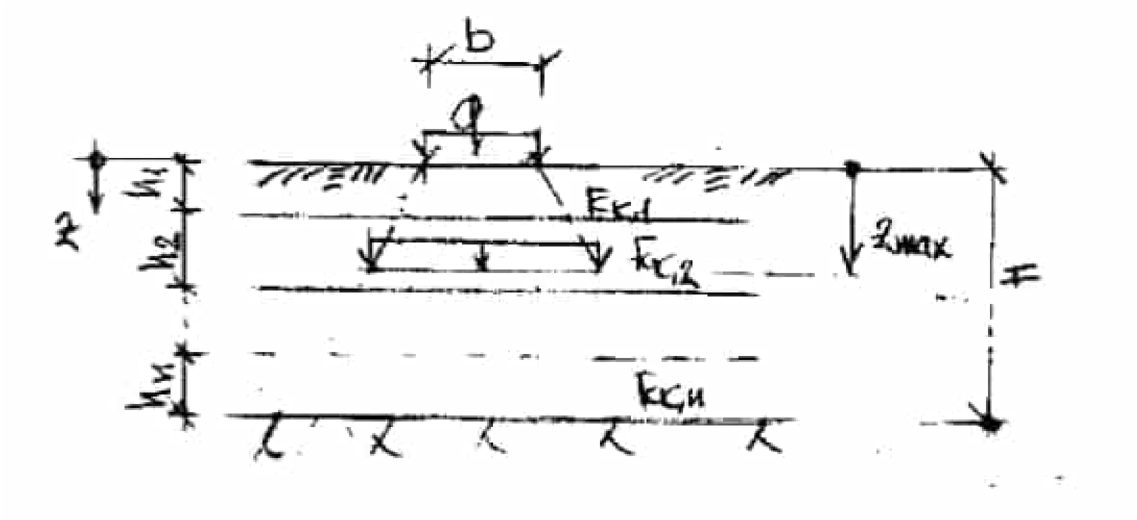
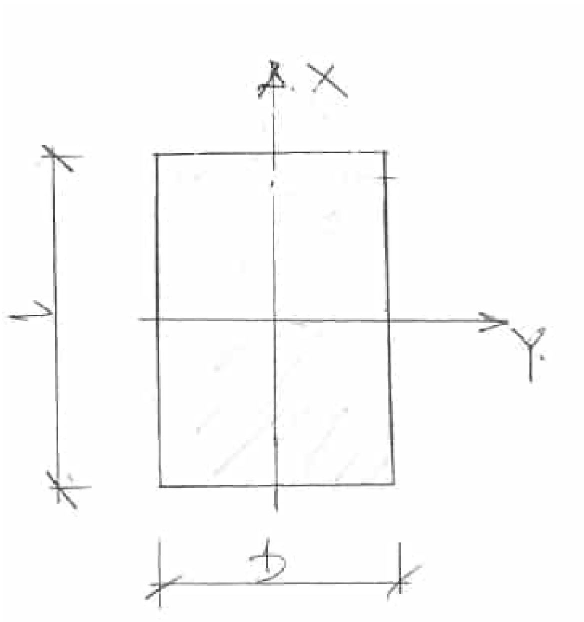
PRINCIPLE SKETCH

Geometry and foundation

The calculation of the equivalent stiffness in the foundation has been carried out according to TRVINFRA-00227, Appendix 4 (method 1). The equivalent E-modulus assumes a load spread of 2:1. The determination was made for a fictitious load corresponding to q (= 100 kPa).

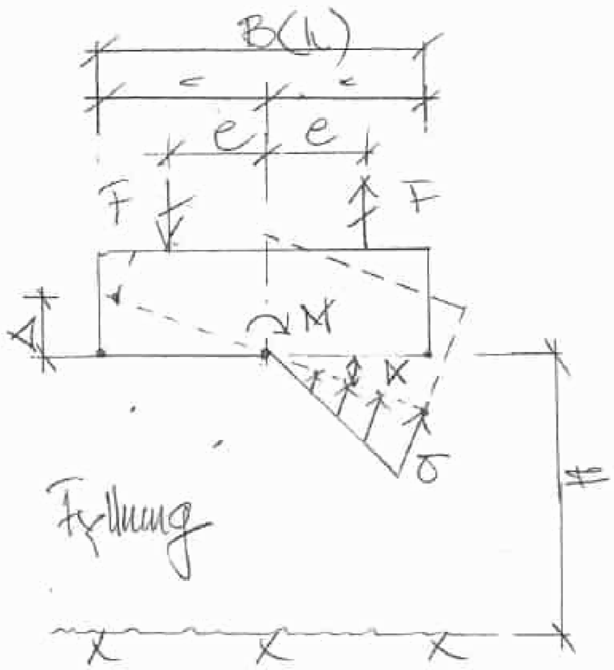




THEORY

When the distance to the rock is less than 2B, the formula below is applied, which also appears in BH page 594 (section 6.4:22 Calculation model).

When distance to rock is greater than 2B use TRVINFRA-00227, Appendix 5.



$$\Delta = \alpha \cdot \frac{B}{2} ; \qquad \varepsilon = \frac{\Delta}{H} = \frac{\alpha \cdot \frac{B}{2}}{H}$$

$$\sigma = \varepsilon \cdot E'_k = \frac{E'_k \cdot \alpha \cdot B}{2 \cdot H}$$

$$F = \sigma \cdot \frac{B}{2} \cdot \frac{1}{2} \cdot L = \frac{E'_k \cdot \alpha \cdot B}{2 \cdot H} \cdot \frac{B \cdot L}{4} = \frac{E'_k \cdot \alpha \cdot B^2 \cdot L}{8 \cdot H}$$

$$M = F \cdot 2e ; \qquad e = \frac{B}{3} ;$$

$$M = F \cdot \frac{2 \cdot B}{3} = \alpha \cdot \frac{L \cdot B^3 \cdot E'_k}{12 \cdot H}$$

$$\Rightarrow \frac{\alpha}{M} = \frac{12 \cdot H}{L \cdot B^3 \cdot E'_k}$$

2.7 SEARCH AREA

Discrete load can be applied to structure as geometrical load areas. In FEM-program load areas are termed Search Area.

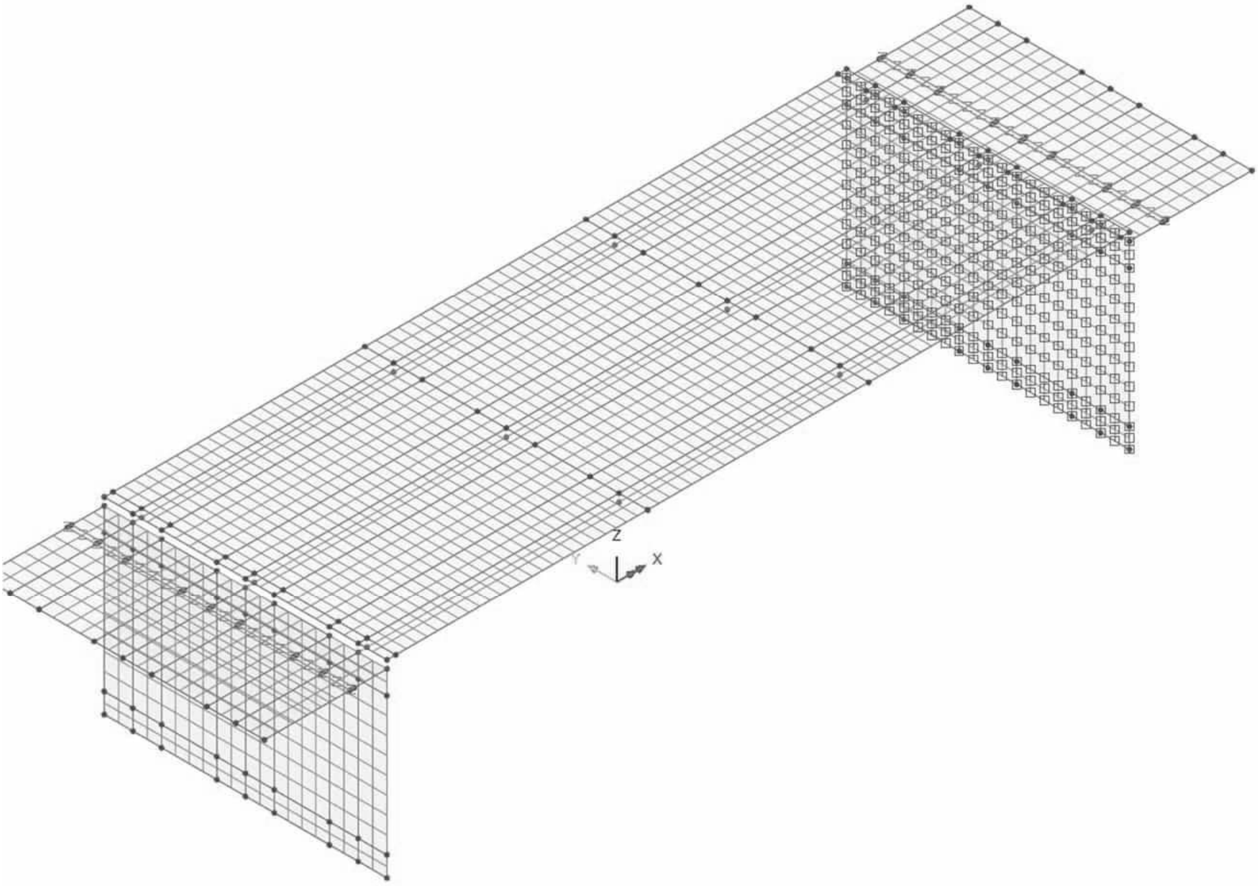
2.7.3 Search area : Abutment 2



2.8 SLICE RESULTANTS BEAMS/SHELLS

Equivalent section forces will be determined at 8 sub-points for each main beam. This is done by studying load effects in the Nodal surface and Nodal line for the respective main beams LB 1 and LB 2.

FEM-program has a script called "Slice Resultant Beams/Shells" to handle this, see the presentation below.

Beam	Path line	Extent	Remark
LB1	800	Slice LB1	Width = 5.10 m
LB2	801	Slice LB2	Width = 5.10 m
LB3	802	Slice LB3	Width = 5.10 m

2.9 FLANGE WIDTH

Flange width is determined by SS-EN 1992-1-1 section 5.3.2.1.

Verification shows that no reduction cross section is needed in “midspan”.

I are area 5 m (∴ 0.15 m ·33.6 m) from abutment a reduction of cross section is needed when studying capacity.

$l_1 = 8.2m$: length abutment

$l_2 = 33.6m$: length superstructure

Verification ”midspan” :

$l_0 = 0.70 l_2 = 0.70 \cdot 33.6m = 23.5m$

$\min(0.2b_1 + 0.1l_0; 0.2l_0, b_1) = \min(0.2 \cdot 1.25m + 0.1 \cdot 23.5m\ ; 0.2 \cdot 22.1m, 1.25m) = 1.25m$

$\rightarrow b_{ef.1} = 1.25m$

Verification “support” :

$l_0 = 0.15 \cdot (l_1 + l_2) = 0.15 \cdot (8.2m + 33.6m) = 6.3m$

$\min(0.2b_1 + 0.1l_0; 0.2l_0, b_1) = \min(0.2 \cdot 1.25m + 0.1 \cdot 6.3m\ ; 0.2 \cdot 6.3m, 1.25m) = 0.88m$

$\rightarrow b_{ef.1} = 0.88m$

- Waterproofing layer 5 mm

$\gamma = 23\frac{kN}{m^3}$: course

$q_{matta} = 0.11kPa$: waterproofing

Surfacing load is seen below:

3.2.2 Load on link slab

On the upper side of the link plate, there is a 95 mm pavement and an overfill with varying thickness (100-400 mm).

The overfill is considered equivalent to the base layer. In the static model, a fictitious load corresponding to the weights for the pavement and overfill is introduced (an average thickness of 250 mm is applied.

$$q_{belägg} = 2.2kPa + 22\frac{kN}{m^3} \cdot 0.25m = 8.0kPa$$

3.3 EARTH PRESSURE

Load applied to Analysis : *Analysis 1*

Earth pressure in filling corresponds to coarse crushed blasted rock (AMA CEB.524).

φ_k = 45°

$\gamma = 20\frac{kN}{m^3}$

$\gamma' = 13\frac{kN}{m^3}$

$$X_d = \frac{1}{\gamma_m} \cdot \eta \cdot \overline{X} \equiv \frac{1}{\gamma_m} \cdot X_k$$

Earth pressure coefficient for design method 2 (D2) :
Design coefficients associated to *A1 + M1 + R2* according to SS-EN 1997-1 section 2.4.7.3.4.3 is applied.

$\gamma_{m.D2}$ = 1.0 : see TSFS chapter 38 table 38.3 for M1

$\rightarrow \varphi_d = artctan\left(\frac{tan\varphi_k}{\gamma_{m.D2}}\right) = arctan\left(\frac{tan45°}{1.0}\right) = 45°$

$K_0 = 1 - \sin(\varphi_d) = 0.29$

$K_a = tan^2\left(45° - \frac{\varphi_d}{2}\right) = 0.17$

$K_p = tan^2\left(45° + \frac{\varphi_d}{2}\right) = 5.82$

Earth pressure for design method 3 (D3) :
Design coefficients associated to *A1(design loads)* + *A2(geotechnical loads)* + *M2* + *R3* according to SS-EN 1997-1 section 2.4.7.3.4.4 is applied.

$\gamma_{m.D3}$ = 1.3 : see TSFS chapter 8 table 38.3 för M2

$\rightarrow \varphi_d = artctan\left(\frac{tan\varphi_k}{\gamma_m}\right) = arctan\left(\frac{tan45°}{1.3}\right) = 38°$

Remark
These are not used used in FEM-analysis. This is done by adjusting load coefficients.

Earth pressure in FEM-analysis:

During design earth press coefficients associated to method D2 will used applied, however the load coefficients are adjusted according verification, see pages A3:170.

K_0 = 0.29

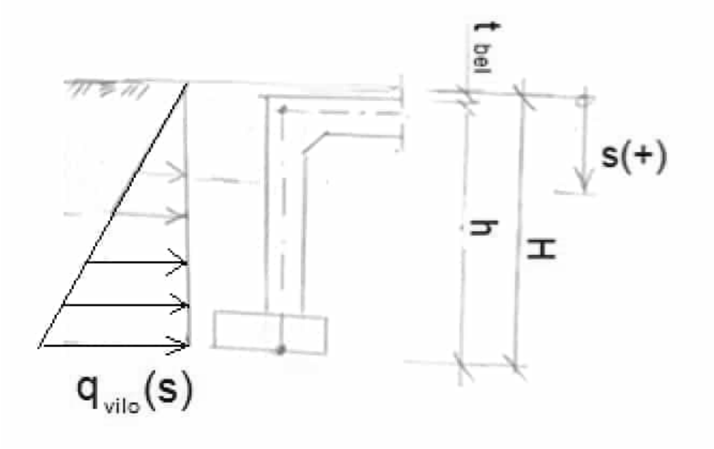
K_a = 0.17

K_p = 5.82

h = 0.90m + 6.085m + 1.70m = 8.685m

H = 0.095m + 8.685m = 8.78m

$$q_{vilo}\,(s) = K_0 \cdot \gamma \cdot s = 0.29 \cdot 20 \frac{kN}{m^3} \cdot s(+) = s(+) \cdot 5.8kPa$$



Remark
Load width B = 12.8 is used for the bottom slab even though width B = 13.3 m. This simplification is possible since favorable effect of passive earth pressure has not been considered on safe side.

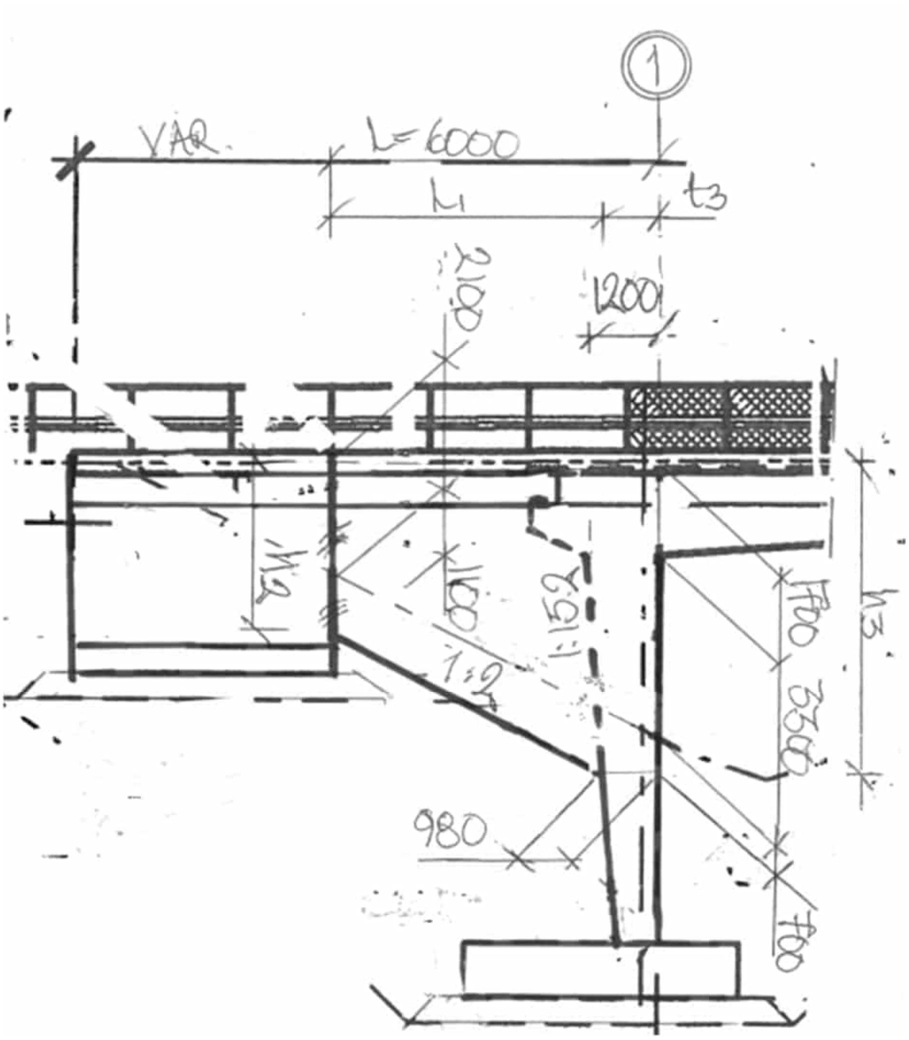
3.3.3 Load against wingwalls

Design software K2.002 is used to determine earth pressure against wingwalls according to Culmans´s theory. All wingwalls are assumed to have same length (L = 6 m).

Load is distributed along edge of abutments from bottom of superstructure and distance 6.08 m downward. This assumption is on safe side.



$$t_3 = \frac{0.98m + 1.20m}{2} = 1.09m \rightarrow L_1 = L - t_3 = 6.0\ m - 1.09\ m = 4.91\ m$$

$$h_2 = 0.10m + 2.10m + 1.10m = 3.30m$$

$$h_3 = 0.10m + 1.70m + 4.00m = 5.80m$$

$$h_4 = 0.10m$$

Effective height along edge abutment:

$H_{ef} = 5.0m$: see page A3:30

Load at abutment edge quasi-load status (SLS-Q):

$N_{SLS-Q} = +81\frac{kNm}{m}$: see page A3:30

$M_{SLS-Q} = 207\frac{kNm}{m}$: see page A3:30

Characteristic earth pressure at abutment edge:

Load below is distributed along length 6.08 m in FEM-model.

$$N_{jord} = +81\frac{kN}{m} \cdot \frac{1}{1.34} = 60\frac{kN}{m}$$

$$M_{jord} = 207\frac{kNm}{m} \cdot \frac{1}{1.34} = 154\frac{kNm}{m}$$

3.4 SUPPORT SETTLEMENT

Load applied to Analysis : *Analysis 1*

Load effect of support settlement shall be considered in TRVINFRA-00227 section 7.2.1.1.1.1.

Only horizontal support displacement in the longitudinal direction of the bridge needs to be considered. Additionally, it is stated that horizontal and vertical support displacements do not need to be combined.

A horizontal support displacement in the longitudinal direction of the bridge (x-direction) of ±5 mm for each support is applied.

Vertical settlement difference (Z-direction) corresponding to support settlement of 10 mm is assumed to occur for all supports.

A verification will be performed to demonstrate that this is on the safe side.

Horizontal displacement (X-direction) amounts to ±10 mm.

When determining associated load effects, reduction is carried out with consideration to creep and cracking.

Note:
The impact of support settlement in serviceability limit state (SLS) according to SS-EN 1992-1-1 §2.3.1.3. If this occurs, a gradual crack development should be applied according to SS-EN 1992-1-1 §5.4(3). Reduction is carried out with consideration to creep and cracking.

The impact of support settlement is not considered in the ultimate limit state (ULS) according to SS-EN 1992-1-1 §2.3.1.3 for this type of bridge.

3.5 CREEP

Total creep is determined according to SS-EN 1992-1-1 §3.1.4 and TRVINFRA-00227 section 7.1.6.4 for RH 80% at time t_1.

Time for first loading (= time when formwork was removed) is termed t_0.

$t_0 = 5\ days$

$t_1 = 120\ years$

Bridge consists of parts with different thicknesses as seen below.

Creep is determine using Mathcad program PROG A001.

Substructure (b = 12.8 m; C35/45):
For t = 0.80 m → $\phi(t_1, t_0) = 1.95$: see page A3:49
For t = 1.20 m → $\phi(t_1, t_0) = 1.93$: see page A3:49

Superstructure (b = 2.60 m; C40/50):
For t = 1.20 m → $\phi(t_1, t_0) = 1.76$: see page A3:49
For t = 1.70 m → $\phi(t_1, t_0) = 1.73$: see page A3:49

Creep $\phi(t_1, t_0) = 1.70$ is used for the entire bridge on safe side since reduces stiffness and associated constraint forces ($\therefore$ support settlement, shrinkage and temperature).

$$\varepsilon_{cc}(t_1, t_0) = \varphi(t_1, t_0) \cdot \frac{\sigma_c}{E_c}$$

To study the effect concrete stiffness according to SS-EN 1992-1-1 5.8.7 creep values seen below are used.

Load cases	φ
Permanent	1.9
Variable excluding temperature	0
Temperature	0.3*

* = According to Swedish work practice

$$E^{system} = \frac{E_{cm}}{1+\varphi}$$

Instead of adjusting E-modulus the load coefficients are adjusted.

$$f_{KRYMP} = \frac{1}{1+\varphi_{ef}} = \frac{1}{1+1.70} = 0.37$$

$$f_{STÖD} = \frac{1}{1+\varphi_{ef}} = \frac{1}{1+1.70} = 0.37$$

$$f_{JTEMP} = \frac{1}{1+\varphi_{ef}} = \frac{1}{1+0.3} = 0.77$$

<u>Note:</u>
According to TRVINFRA-00227 section 7.2.1.1.2.4, no reduction is permitted for uneven temperature across the cross-section. This is because this temperature variation is considered to have a very short duration (only over the day).

3.6 SHRINKAGE

Load applied to Analysis : *Analysis 2*

Total shrinkage according to SS-EN 1992-1-1 §3.1.4 and TRVINFRA-00227 section 7.1.6.4 for RH 80% at time t_1.

Determination of load effect from shrinkage should consider the reduced concrete stiffness from creep.

$t_s = 0\ days$

$t_1 = 120\ years$

Shrinkage is determined using Mathcad program PROG A002 after time t_1.

Substructure (b = 12.8 m; C35/45):
For t = 0.80 m → $\varepsilon_{cs}\ (t_1) = 0.024\%$: see page A3:53
For t = 1.20 m → $\varepsilon_{cs}\ (t_1) = 0.023\%$: see page A3:53

Superstructure (b = 2.60 m; C40/50):
For t = 1.20 m → $\varepsilon_{cs}\ (t_1) = 0.025\%$: see page A3:53
For t = 1.70 m → $\varepsilon_{cs}\ (t_1) = 0.024\%$: see page A3:53

Shrinkage $\varepsilon_{cs} = 0.025\%$ is applied to all construction parts for safety. The movement corresponds to that which occurs due to an imaginary temperature load ∴ T = -25°C.

Remark
Shrinkage must be considered for service state (SLS) see SS-EN 1992-1-1 §2.3.2.2(1).

Shrinkage does not have to be used for ultimate state (ULS) see SS-EN 1992-1-1 §2.3.2.2(2).

3.8 BRAKING LOAD

Load applied to Analysis : *Analysis 1*

Braking load is defined by SS-EN 1991-2 §4.4.1.

Load acts at level of surfacing.

L = 1.75 m + 32.8 m + 1.75 m = 36.3 m

Load modell LM 1 :

$$Q_{lk} = 0.6\alpha_{Q1} \cdot (2Q_{ik}) + 0.1\alpha_{q1} \cdot q_{1k} \cdot w_1 \cdot L$$

$$180kN \cdot \alpha_{Q1} \leq Q_{lk} \leq 900kN$$

$$Q_{broms} = 0.6 \cdot (2 \cdot 270kN) + 0.1 \cdot 7.2kPa \cdot 3.0m \cdot 36.3m = 324kN + 78kN = 402kN$$

Load modell EG B = 300 kN (see TSFS chapter 11 §2) :

Typ o is dimensioning.

$$Q_{lk} = 0.35 \cdot \sum Q_{EG\ B} + 0.1 \cdot p \cdot L_q$$

$$Q_{lk} \leq 500kN$$

$$Q_{broms} = 0.35 \cdot (0.89 + 1.17 + 0.83 + 0.89) \cdot B = 0.35 \cdot 3.78 \cdot 300kN = 397kN$$

Note:
The braking force associated with LM 1 is applied on the safe side in the system calculation.

The impact of the resisting earth pressure against the frame legs is neglected on the safe side.

3.8.1 Load definition

The load is introduced as a surface load in the bridge deck's system line, located 0.25 meters below the pavement level. In the static model, this is disregarded since the effect of load my is small.

To avoid considering varying load placement laterally, it is assumed that two braking forces occur symmetrically on the bridge deck. This simplification of braking forces is considered safe.
The braking force is considered evenly distributed over the entire bridge deck.

$$q_x = 2 \cdot \frac{Q_{broms}}{w_{tot} \cdot L_{deck}} = 2 \cdot \frac{402kN}{12.8m \cdot 33.6m} = 1.9\frac{kN}{m^2}$$

$$m_y = q_x \cdot (0.15m + t_{bel}) = 1.9\frac{kN}{m^2} \cdot (0.15m + 0.10m) = 0.5\frac{kNm}{m^2}$$

3.9 LATERAL FORCE

Load applied to Analysis : *Analysis 1*

Lateral force is defined by SS-EN 1991-2 §4.4.2.

The load is orthogonal to braking force and acts due to skewed braking.

The acting load acts at the level of the pavement and evenly distributed over the load length.

Load model LM 1 :

$Q_{tk} = 0.25Q_{lk} = 0.25 \cdot 402kN = 100kN$: skewed braking

Load model EG B = 300 kN (see TSFS chapter 11 §2) :

$Q_{tk} = 0.25Q_{lk} = 0.25 \cdot 397kN = 69kN$: skewed braking

Last definition:
The load is applied as a surface load on the system line of the bridge deck, which is located 0.35 m below the pavement level. In the static model, the impact of m_x is not considered as it is deemed negligible.
To avoid considering varying load placement longitudinally, it is assumed that two lateral forces occur symmetrically on the bridge deck. This simplification of lateral forces is considered safe.
The lateral force is considered evenly distributed over the entire bridge deck.

$$q_y = 2 \cdot \frac{Q_{sido}}{w_{tot} \cdot L_{deck}} = 2 \cdot \frac{100kN}{12.8m \cdot 33.6m} = 0.5\frac{kN}{m^2}$$

$$m_x = q_y \cdot (0.15m + t_{bel}) = 0.5\frac{kN}{m} \cdot (0.15m + 0.10m) = 0.1\frac{kNm}{m^2}$$

$$p_{vind}^{bro} = \frac{F_w}{L} = \frac{1}{2} \cdot \rho \cdot v_b^2 \cdot C \cdot \frac{A_{ref.x}^{bro}}{L} = \frac{1}{2} \cdot 1.25 \frac{kg}{m^3} \cdot \left(22 \frac{m}{s}\right)^2 \cdot 2.61 \cdot 1.55m = 1.2 \frac{kN}{m}$$

Wind load traffic (above pavement) :

$$\frac{A_{ref.x}^{traf}}{L} \equiv d_{traf}$$

$$p_{vind}^{traf} = \frac{F_w}{L} = \frac{1}{2} \cdot \rho \cdot v_b^2 \cdot C \cdot \frac{A_{ref.x}^{bro}}{L} = \frac{1}{2} \cdot 1.25 \frac{kg}{m^3} \cdot \left(22 \frac{m}{s}\right)^2 \cdot 2.61 \cdot 2.00m = 1.6 \frac{kN}{m}$$

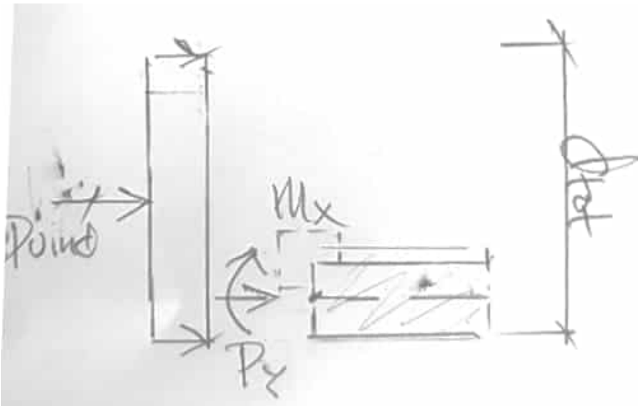
When traffic load acts om bridge together load associated to traffic can be reduced according to SS-EN 1991-1-4 section 8.1 (4). However this reduction is not considered on safe side.

$$* p_{vind}^{traf} = \psi_0 \cdot \frac{F_w}{L} = \psi_0 \cdot \frac{1}{2} \cdot \rho \cdot v_{b.0}^2 \cdot C \cdot \frac{A_{ref.x}^{bro}}{L} = 0.3 \cdot \frac{1}{2} \cdot 1.25 \frac{kg}{m^3} \cdot \left(23 \frac{m}{s}\right)^2 \cdot 2.61 \cdot 2.00m$$
$$= 0.5 \frac{kN}{m}$$

3.10.1 Definition of load

Load is applied as a line load acting along each edge beam.

$$p_{vind} = p_{vind}^{bro} +* \, p_{vind}^{traf} = 1.2\frac{kN}{m} + 1.6\frac{kN}{m} = 2.8\frac{kN}{m}$$



$$\rightarrow \quad p_y = 3\frac{kN}{m}$$

$$m_x = -p_y \cdot \left[\frac{d_{tot}}{2} - (1.45m - 0.50m)\right] = -3\frac{kN}{m} \cdot \left[\frac{3.55m}{2} - 0.95m\right] = -3\frac{kNm}{m}$$

$q_{ytlast.2} = 10kPa$: remaining width

On the safe side, a surface load of 20 kPa is applied to the entire bridge width of 12.8 meters.

The favourable impact of the counteracting earth pressure due to movement is not accounted for on the safe side.

13.12.1 Effect of concrete stiffness due to cracking

Impact is considered in the serviceability limit state according to SS-EN 1992-1-1 §2.3.1.2 (1). If this is done, a gradual development of cracking may be applied according to SS-EN 1992-1-1 §5.4(3).

In the studied bridge, all concrete is assumed to be cracked for the load cases of temperature, support settlement, and creep.

This assumption will be verified to ensure that it is accurate. If it is not, the calculation model will be adjusted accordingly.

Verification of whether the concrete is cracked will be done according to SS-EN 1992.2 section 7.2 (102) under the condition $\sigma_{ct}^{SLS-K} > f_{ctm}$.

A review of the bending stiffness according to SS-EN 1992-1-1 shows that completely uncracked reinforced concrete has a stiffness that is 13% of the cracked concrete according to SS-EN 1992-1-1 section 7.4.3 when applied to a slab with a thickness of 1200 mm, see page A3:116.

Selected bending stiffness in the calculation model:

In the chosen calculation, standard Swedish calculation practice is applied with stiffness of 60% for cracked compared to uncracked concrete.

Uncracked section (stage I): $EI_{osprucket} = EI_{I} = E_{cm} \cdot I_{c}$

Cracked section (stage II): $EI_{sprucket} = EI_{II} = 0.6 E_{cm} \cdot I_{c}$

Evaluation of bending stiffnesses according to SS-EN 1992-1-1 :

The control is performed for a section corresponding to b x h = 1000 mm x 1200 mm and reinforcement ϕ16s250 (∴ 804 mm^2/m).

The evaluation of stiffness for stage II (cracked section) is done using the calculation program caeEc205.

$$I_I = \frac{b \cdot h^3}{12} = \frac{1.0m \cdot (1.20m)^3}{12} = 144 \cdot 10^{-3} m^4$$: uncracked crossection

$$I_{II} = 18 \cdot 10^{-3} m^4$$: cracked crossection, see page A3: 116

$\rightarrow \eta = \frac{I_{II}}{I_I} = 13\% < 60\,\%$ thus on safe side !

3.12.2 Even temperature over entire bridge (JTEMP)

Even temperature over entire bridge according to EN 1991-1-5 section 6.1.3.3. This temperature change is seasonal.

Uniform temperature change across the entire bridge is given by EN 1991-1-5, section 6.1.3.3. This temperature change is seasonal and primarily causes translation from the bridge's movement center towards the respective supports. This movement is considered to give rise to increased earth pressure due to the movement.

Function according to SS EN 1991-1-5 sketch 6.1 (bridge type 3) :

$$T_e(T) = \mathrm{linterp}\left[(-50 \;\; 0 \;\; 30 \;\; 50)^T \cdot °C, (-42 \;\; 7 \;\; 32 \;\; 52)^T \cdot °C, T\right]$$

$$T_{e.max} = T_e\left(T_{max}\right) = 36\,°C$$

$$T_{e.min} = T_e\left(T_{min}\right) = -34\,°C$$

$$T^+ = T_{e.max} - T_0 = +36℃ - 10℃ = +26℃$$

This load corresponds to what is stated in SS-EN 1997-1, section C.3. This section is used to ensure that movements for Δq(s) do not exceed the limit for passive earth pressure. During this check, "firm ground" and "wall movement type" b are applied. . Vid denna kontroll tillämpas ”fast jord” och ”väggens rörelsesätt” typ b.

$k_{1.sur}(t = 100mm) = 0.7$

$\Delta T_{max} = +15°C \cdot k_{1.sur} = +11°C$: : upper surface warmer

$\Delta T_{min} = -8°C \cdot k_{2.sur} = -8°C$: : lower surface warmer

The occurring temperature change ΔT refers to the linear difference between the temperature at the top and bottom of the bridge deck slab.

Uneven temperature is indicated as a temperature gradient $\frac{\delta T}{\delta Z}$ when defined in FEM-program.

The load effect is added to longitudinal beams with varying height (D: 0.90 m → 1.40), see page A2:24. On safe side δZ = 0.9 m is assumed.

$\frac{\delta T^{max}}{\delta Z} = \frac{+11°C}{0.90m} = +12\frac{°C}{m}$: maximal temperature gradient

3.13 PRESTESS

Load applied to Analysis : *Analysis 1*

Analysis of pre tensioned cable is studied at times : t_0 (5 days), t_1(30 days) and t_2 (120 years).

The preliminary location of cables is determined with program PROG B2.001.

The location is imported as a spread sheet into FEM-program as a tension profile. The location is defined with local coordinates associated to nodal lines (LB 1-3).

Initial prestress loss at time t0 is only due to friction. This is determined with FEM-program and program PROG B2.001.

Determination of time loses (η_t) is made in separate program PROG B2.002. Preliminary analysis will use losses seen below. They will be verified later during detailed design.

Time	η_t	Load combination	Load case
t0	0 %	PT-T0	1.00 x PT-T0
t1	6 %	PT-T1	0.94 x PT-T0
t2	16 %	PT-T2	0.84 x PT-T0

3.13.3 Preliminary cable location

In the static model cables are simplified (= 4 cables are modelled as one fictive cable as seen below).

Profiles can be defined using "global coordinates" or as "local coordinates mapped to lines". The later of this method is used. The nodal lines associated to LB 1, LB 2 and LB 3 are used.

3.14 LOAD COMBINATIONS

Verification of load capacity shall be carried out for several limit states as detailed in this section.

Fatigue Limit State:
The risk of fatigue according to the partial factor method is checked using equation 6.69 provided in document SS-EN 1992-1-1.

Other Limit States:
For other limit states, section 6.4.3 of EN-1990 is applied.

3.14.1 Ultimate Limit States (ULS)

When checking the ultimate limit state, the load factors vary depending on the type of failure as detailed below:

STR: Verification of structural bearing capacity

GEO: Verification of geotechnical bearing capacity

For checking the ultimate limit state, TRVNFRA-00227 section 7.1.6.3 specifies requirements for load combinations as follows.

Design Method D2 (Set B):
Design Method D2 (Set B) according to TSFS 2018:57 Table 4.4 shall be applied for the structural bearing capacity of the construction (STR; SK 3).

Design Method is defined according to EN-1990 equations 6.10a and 6.10b as detailed below.

$$E_{Sd}^{10a} = \sum_{j\geq 1} \gamma_{G.j} \cdot G_{k,j} + \gamma_{Q.1} \cdot \psi_{0,1} \cdot Q_{k.1} + \sum_{i>1} \gamma_{Q.i} \cdot \psi_{0,i} \cdot Q_{k,i} = \psi\gamma_{ULS-A} \cdot (\sum_{j>1} G_{k,j} + \sum_{i>1} Q_{k,i})$$

$$E_{sd}^{10b} = \sum_{j\geq 1} \xi_j \cdot \gamma_{G.j} \cdot G_{k,j} + \gamma_{Q.1} \cdot Q_{k.1} + \sum_{i>1} \gamma_{Q.i} \cdot \psi_{0,i} \cdot Q_{k,i} = \psi\gamma_{ULS-B} \cdot (\sum_{j>1} G_{k,j} + \sum_{i>1} Q_{k,i})$$

Equation 6.10a refers to the (ULS-A) case where the permanent loads are dominant, usually during the construction phase.

Equation 6.10b refers to the (ULS-B) case where the variable loads are dominant.
Design method 2 (set B) according to TSFS 2018:57 table 4.4 shall be applied for the structural capacity (STR; SK3).

A1 (construction loads)
All load factors are greater than set C.

A2 (geotechnical loads)

- Load coefficient earth pressure:
  $\psi\gamma_{\mathrm{ULS-A}} = \gamma_{\mathrm{d}} \cdot 1.35 \cdot \eta_{\mathrm{sup.G}} = 1.0 \cdot 0.89 \cdot 1.35 \cdot 1.1 = 1.49$ ← dimensioning
  $\psi\gamma_{\mathrm{ULS-B}} = \gamma_{\mathrm{d}} \cdot 0.89 \cdot 1.35 \cdot \eta_{\mathrm{sup.G}} = 1.0 \cdot 0.89 \cdot 1.35 \cdot 1.1 = 1.33$

- Load coefficient surcharge:
  $\psi\gamma_{\mathrm{ULS-A}} = \gamma_{\mathrm{d}} \cdot \psi_0 \cdot 1.50 = 1.0 \cdot 0.75 \cdot 1.50 = 1.13$
  $\psi\gamma_{\mathrm{ULS-B}} = \gamma_{\mathrm{d}} \cdot 1.50 = 1.0 \cdot 1.50 = 1.50$ ← dimensioning

Design method D3 (set C):

Design method D3 (set C) according to TSFS 2018:57 table 4.5 shall be applied for determining geotechnical bearing capacity (GEO; SK 2).

The design method is defined according to EN-1990 equation 6.10a and 6.10b as presented below.

$$E_{Sd}^{10a} = \sum_{j\geq 1} \gamma_{G.j} \cdot G_{k,j} + \gamma_{Q.1} \cdot \psi_{0,1} \cdot Q_{k.1} + \sum_{i>1} \gamma_{Q.i} \cdot \psi_{0,i} \cdot Q_{k,i} = \psi\gamma_{ULS-GA} \cdot (\sum_{j>1} G_{k,j} + \sum_{i>1} Q_{k,i})$$

$$E_{sd}^{10b} = \sum_{j\geq 1} \xi_j \cdot \gamma_{G.j} \cdot G_{k,j} + \gamma_{Q.1} \cdot Q_{k.1} + \sum_{i>1} \gamma_{Q.i} \cdot \psi_{0,i} \cdot Q_{k,i} = \psi\gamma_{ULS-GB} \cdot (\sum_{j>1} G_{k,j} + \sum_{i>1} Q_{k,i})$$

Equation 6.10a refers to the (ULS-A) case where the permanent loads are dominant, usually during the construction phase.

Equation 6.10b (ULS-B) refers to the case where the variable loads are dominant.

Design method 3 (set C) according to TSFS 2018:57 table 4.5 shall be applied for determining geotechnical bearing capacity (GEO).

A1 (construction loads)
All load factors are less than set B.

A2 (geotechnical loads)
- Load coefficient earth pressure: $\psi\gamma_{jord} = \gamma_d \cdot 1.1 \cdot \eta_{sup.G} = 0.91 \cdot 1.1 \cdot 1.1 = 1.10$

- Load coefficient surcharge: $\psi\gamma_{\text{över}} = \gamma_d \cdot 1.40 = 0.91 \cdot 1.40 = 1.27$

Simplified Design Method ULS:

To limit the number of load combinations, design method D2 (STR) is also applied for checking geotechnical bearing capacity (GEO). This is done by adjusting load coefficients associated with the geotechnical loads.
When applying the geotechnical loads, the earth pressure coefficient corresponding to D2 is applied.

Check load coefficients associated with the geotechnical loads

$K_o(D2) = 1 - sin(\varphi_d) = 1 - sin45^{\circ} = 0.29$

$K_o(D3) = 1 - sin(\varphi_d) = 1 - sin38^{\circ} = 0.39$

Earth pressure→ 1.48[1.)] $\cdot K_0(D2) = 0.43 \equiv 1.10 \cdot K_0(D3) = 0.43$ i.e. OK!

Surcharge → 1.71[2.)] $\cdot K_0(D2) = 0.43 \equiv 1.27 \cdot K_0(D3) = 0.50$ i.e. OK!

1.) Last coefficient $\psi\gamma_{ULS} = 1.48$ is applied instead of 1.33.

3.14.2 Service limit state (SLS)

The service limit state is divided into 3 load combinations based on their duration. The load combinations are presented below.

Load combination	Duration
SLS:K	Characteristic
SLS:F	Frequent
SLS:Q	Quasi-permanent

Load Combination SLS:K according to EN 1990 equation 6.14b is presented below.

$$E_{Sd} = \sum_{j\geq 1} G_{k,j} + Q_{k.1} + \sum_{i>1} \psi_{0,i} \cdot Q_{k,i} = \psi\gamma_{SLS.K} \cdot (\sum_{j>1} G_{k,j} + \sum_{i>1} Q_{k,i})$$

Load Combination SLS:F according to EN 1990 equation 6.15b is presented below.

$$E_{Sd} = \sum_{j\geq 1} G_{k,j} + \psi_1 \cdot Q_{k.1} + \sum_{i>1} \psi_{2,i} \cdot Q_{k,i} = \psi\gamma_{SLS.2} \cdot (\sum_{j>1} G_{k,j} + \sum_{i>1} Q_{k,i})$$

Load Combination SLS:Q according to EN 1990 equation 6.16b is presented below.

$$E_{Sd} = \sum_{j\geq 1} G_{k,j} + \sum_{i>0} \psi_{2,i} \cdot Q_{k,i} = \psi\gamma_{SLS.Q} \cdot (\sum_{j>1} G_{k,j} + \sum_{i>1} Q_{k,i})$$

When designing, load coefficients according to equations 6.14a, 6.15b, and 6.16b are applied. Refer to the derivation in Appendix 2.

Adjustment of load coefficients for geotechnical loads:

$K_o(D2) = 1 - sin(\varphi_d) = 1 - sin45^{\circ} = 0.29$

$K_o(D3) = 1 - sin(\varphi_d) = 1 - sin38^{\circ} = 0.39$

LC	Earth pressue
SLS-K	$\frac{K0(D3)}{K0(D2)} \cdot 1.1 = \frac{0.39}{0.29} \cdot 1.1 = 1.48$
SLS-F	$\frac{K0(D3)}{K0(D2)} \cdot 1.1 = \frac{0.39}{0.29} \cdot 1.1 = 1.48$
SLS-Q	$\frac{K0(D3)}{K0(D2)} \cdot 1.0 = \frac{0.39}{0.29} \cdot 1.0 = 1.34$

3.14.3 Accidental load combination

The accidental load case is also designated as exceptional load combination EXC according to SS-EN 1990 section 6.4.3.3 equation 6.11a as shown below.
The accidental load case is denoted as A_d and consists of cable loss or impact load.

$$E_{Sd} = \sum_{j\geq 1} G_{k,j} + P + A_d + \psi_{1,1} \cdot Q_{k,1} + \sum_{i>1} \psi_{2,i} \cdot Q_{k,i} = \cdots$$

$$\psi\gamma_{EXC} \cdot \left(\sum_{j\geq 1} G_{k,j} + P + A_d + \sum_{i\geq 1} Q_{k,j}\right)$$

3.14.4 Fatigue load combination

Fatigue is considered according to SS EN 1992-1-1, 6.8.4 and 6.8.6, and SS EN 1992-2, 6.8 and Appendix NN.

The risk of fatigue is checked using a simplified method, denoted as the λ-method.
Load combination according to equation SS-EN 1992-1-1 section 6.8.3 equation 6.69.

In this load combination, the traffic load is considered to consist of UTM, whereby other traffic loads are excluded.

$$E_{Sd} = \sum_{j\geq 1} G_{k,j} + P + \psi_{1,1} \cdot Q_{k,1} + \sum_{i>1} \psi_{2,i} \cdot Q_{k,i} + Q_{fat} = \psi\gamma_{UTM} \cdot (\sum_{j\geq 1} G_{k,j} + P + \sum_{i\geq 1} Q_{k,i} + Q_{fat})$$

Load cases BELÄGG, STOD and KRYMP are not fatigue loads, thus load coefficient 1.0 is applied.

Load cases pretension is not a fatigue loads, thus load coefficient lowest load value of value is assumed PT-t2 (= 0.84·PT-t0) is applied.

Load case JORD is not a fatigue load, thus load coefficient highest load coefficient is applied.

Load cases TEMP, VIND and OVER are not fatigue loads, thus load is not considered.

During verification STR, the load case TEMP can be neglected according to SS-EN 1992-1-1 section 2.3.1.2(2).

In the report, the letter “T” is used to describe a range. The letter is an abbreviation of “to”.

See example of assignment below.

Assignment to Lines:
105T110;114T119

This expression means that the assignment occurs to the lines L105 → L110 and L114 → L119.

Assignment to Surfaces:
